CAUTION

Executive Summary

The Lifted Initiative team partnered with Hashlock to conduct a security audit of their Token Factory module. Hashlock manually and proactively reviewed the code in order to ensure the project's team and community that the deployed contracts are secure.

Project Context

The Lifted Initiative is revolutionizing the Web3 landscape by developing a comprehensive framework that seamlessly integrates Web2 and Web3 functionalities, empowering users to create bespoke layer 1 networks without requiring prior blockchain expertise. By contributing to the Many Protocol, Lifted ensures interoperability across various modules and networks, fostering a cohesive decentralized ecosystem. Their commitment to accessibility and sustainability is evident through initiatives like the Liftoff Program, which supports Web3 builders in refining their products and strategies. The Token Factory module allows any user to have granular control over the creation and management of tokens on the Manifest Network. The creator can mint, burn, edit, and transfer tokens to other accounts from any account.

Project Name: Manifest Token Factory
Compiler Version: go version go1.22.5 darwin/arm64
Website: https://liftedinit.org

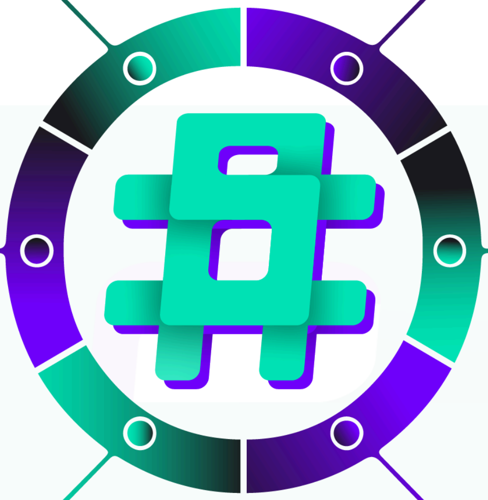
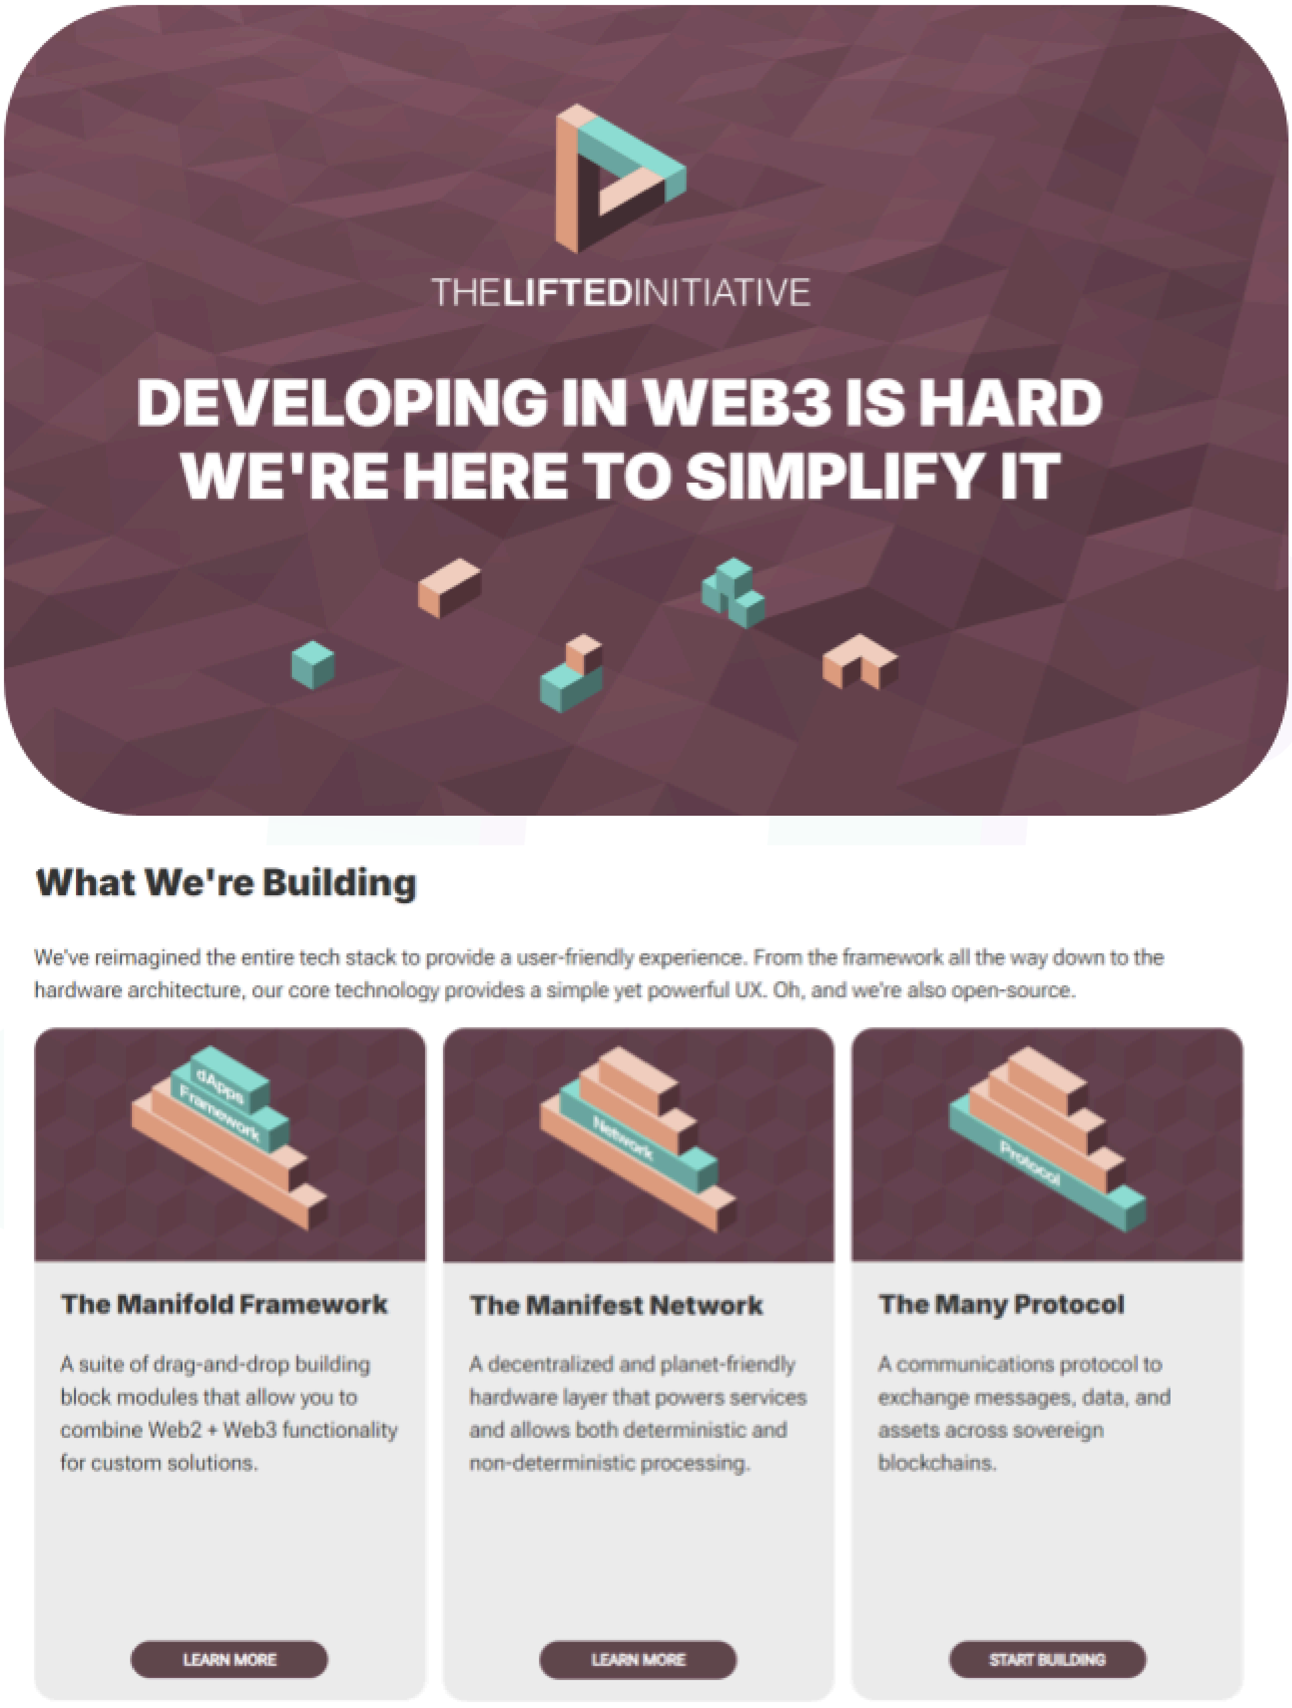
Visualised Context:



Project Name	Manifest
Launch Date	TBA
Compiler Version	go1.22.5 darwin/arm64
Language	Go
Network	Cosmos
Token Ticker	N/A

Project Visuals:



DEVELOPING IN WEB3 IS HARD
WE'RE HERE TO SIMPLIFY IT

What We're Building

We've reimagined the entire tech stack to provide a user-friendly experience. From the framework all the way down to the hardware architecture, our core technology provides a simple yet powerful UX. Oh, and we're also open-source.

The Manifold Framework

A suite of drag-and-drop building block modules that allow you to combine Web2 + Web3 functionality for custom solutions.

The Manifest Network

A decentralized and planet-friendly hardware layer that powers services and allows both deterministic and non-deterministic processing.

The Many Protocol

A communications protocol to exchange messages, data, and assets across sovereign blockchains.

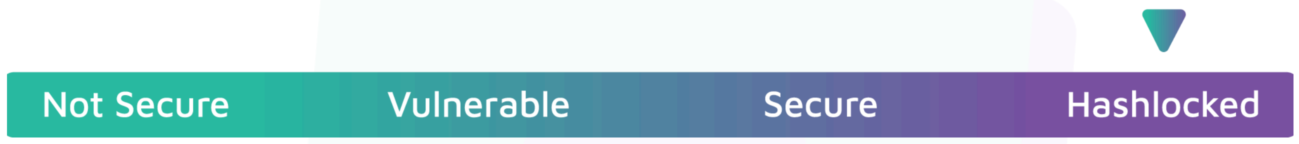
Audit scope

We at Hashlock audited the Go code within the Token Factory module, the scope of work included a comprehensive review of the smart contracts listed below. We tested the smart contracts to check for their security and efficiency. These tests were undertaken primarily through manual line-by-line analysis and were supported by software-assisted testing.

Description	**Token Factory module**
Platform	**Cosmos / Go**
Audit Date	**October, 2024**
Repository URL	https://github.com/strangelove-ventures/tokenfactory
GitHub Commit hash	59eb848fc19920a68d39275d521ae55d8b3d6916

Security Rating

After Hashlock's Audit, we found the smart contracts to be **"Hashlocked"**. The contracts all follow simple logic, with correct and detailed ordering. We initially identified some significant vulnerabilities that have since been addressed.



The 'Hashlocked' rating is reserved for projects that ensure ongoing security via bug bounty programs or on chain monitoring technology.

All issues uncovered during automated and manual analysis were meticulously reviewed and applicable vulnerabilities are presented in the Audit Findings section. The general security overview is presented in the Standardised Checks section and the project's contract functionality is presented in the Intended Smart Contract Functions section.

All vulnerabilities initially identified have now been resolved and acknowledged.

Hashlock found:

2 Medium severity vulnerabilities

1 Low severity vulnerabilities

1 Gas Optimisations

Caution: *Hashlock's audits do not guarantee a project's success or ethics, and are not liable or responsible for security. Always conduct independent research about any project before interacting.*

Intended Smart Contract Functions

Claimed Behaviour	Actual Behaviour
Token Factory - Allows users to: - Create tokenfactory denoms - Mint tokenfactory denoms - Burn tokenfactory denoms - Change admin of a tokenfactory denom - Update a tokenfactory's denom metadata - Force transfer a tokenfactory denom between users - Allows the authority to: - Update the module params	**Module achieves this functionality.**

Code Quality

This audit scope involves the smart contracts of the Token Factory module, as outlined in the Audit Scope section. All contracts, libraries, and interfaces mostly follow standard best practices and to help avoid unnecessary complexity that increases the likelihood of exploitation, however, some refactoring was required.

The code is very well commented on and closely follows best practice nat-spec styling. All comments are correctly aligned with code functionality.

Audit Resources

We were given the Token Factory module code in the form of Github access.

As mentioned above, code parts are well commented. The logic is straightforward, and therefore it is easy to quickly comprehend the programming flow as well as the complex code logic. The comments are helpful in providing an understanding of the protocol's overall architecture.

Dependencies

As per our observation, the libraries used in this smart contracts infrastructure are based on well-known industry standard open source projects.

Severity Definitions

Significance	Description
High	High-severity vulnerabilities can result in loss of funds, asset loss, access denial, and other critical issues that will result in the direct loss of funds and control by the owners and community.
Medium	Medium-level difficulties should be solved before deployment, but won't result in loss of funds.
Low	Low-level vulnerabilities are areas that lack best practices that may cause small complications in the future.
Gas	Gas Optimisations, issues, and inefficiencies
QA	Quality Assurance (QA) findings are purely informational and don't impact functionality. These notes help clients improve the clarity, maintainability, or overall structure of the code, ensuring a cleaner and more efficient project. They should be addressed for optimization but are not critical to the system's performance or security.

Audit Findings

Medium

[M-01] x/tokenfactory/types/capabilities.go#IsCapabilityEnabled - Incorrect return of enabled capabilities leading to unauthorized capabilities

Description

The `IsCapabilityEnabled` function returns `true` if the `enabledCapabilities` length is zero. This is incorrect because if the chain does not enable any capabilities, it should indicate that no capabilities are allowed to be performed.

Impact

Capabilities are incorrectly enabled when the chain intends to disable all of them; thus, unauthorized capabilities will be incorrectly enabled, potentially allowing unintended or malicious operations.

Recommendation

Consider returning `false` if the `enabledCapabilities` length is zero.

Status

Resolved

[M-02] x/tokenfactory/keeper/bankactions.go#mintTo - Sudo admin can mint non tokenfactory denoms

Description

If `types.EnableSudoMint` capability is enabled, a sudo call can be performed by the POA keeper admin. The intended functionality is to allow the sudo admin to mint any tokenfactory denoms to users.

However, the sudo admin can also mint non-tokenfactory denoms, such as the staking denom of the chain. This is because the validation in `x/tokenfactory/keeper/bankactions.go#L16-L21` only checks that the denom to mint is the token factory denom if it is not a sudo call.

Impact

Sudo admin can mint non-tokenfactory denoms, potentially disrupting the chain's token economy.

Recommendation

Consider checking that only tokenfactory denoms can be minted by the sudo admin.

Note

The Lifted Initiative team stated that this behavior was specifically requested by Manifest and is the intended functionality to allow minting without the factory/tokens. The reason for this is that enabling this behavior without creating another module for this small feature would be impractical. They compared it to Linux sudo, where the scope is not limited (otherwise, it would be named something like SudoMintTokenFactory). However, they noted that adding two different kinds of SudoMint would be too confusing.

Status

Acknowledged

Low

[L-01] x/tokenfactory/keeper/msg_server.go#Mint, Burn - Incorrect events emitted

Description

The `types.AttributeMintToAddress` and `types.AttributeBurnFromAddress` attributes are set to `msg.Sender`. This is incorrect if the `Mint` or `Burn` functions are called with `msg.MintToAddress` and `msg.BurnFromAddress` parameters.

Recommendation

Consider setting the `types.AttributeMintToAddress` to `msg.MintToAddress` and the `types.AttributeBurnFromAddress` attribute to `msg.BurnFromAddress`.

Status

Resolved

Gas

[G-01] x/tokenfactory/keeper/admins.go#setAdmin - Duplicate load of `KVStore` increases gas consumption

Description

Inside `setAdmin`, the `GetAuthorityMetadata` function is called to retrieve the metadata for the denom. However, before this function is called in `x/tokenfactory/keeper/msg_server.go#L175`, the metadata is already retrieved in `x/tokenfactory/keeper/msg_server.go#L166`, which can be used during `setAuthorityMetadata`.

Recommendation

Consider refactoring the `setAdmin` function so the `authorityMetadata` variable can be passed directly to the function to avoid calling the `GetAuthorityMetadata` twice.

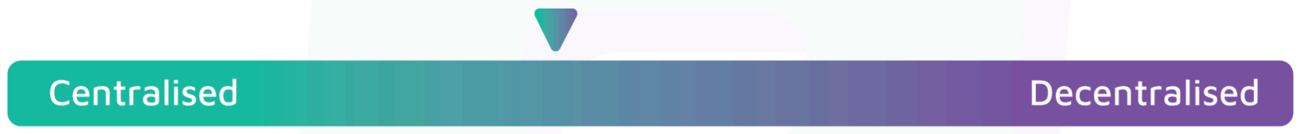
Status

Resolved

Centralisation

The Token Factory project values security and utility over decentralisation.

The owner executable functions within the protocol increase security and functionality but depend highly on internal team responsibility.



Conclusion

After Hashlocks analysis, the Token Factory module seems to have a sound and well-tested code base, now that our vulnerability findings have been resolved and acknowledged. Overall, most of the code is correctly ordered and follows industry best practices. The code is well commented on as well. To the best of our ability, Hashlock is not able to identify any further vulnerabilities.

Our Methodology

Hashlock strives to maintain a transparent working process and to make our audits a collaborative effort. The objective of our security audits is to improve the quality of systems and upcoming projects we review and to aim for sufficient remediation to help protect users and project leaders. Below is the methodology we use in our security audit process.

Manual Code Review:
In manually analysing all of the code, we seek to find any potential issues with code logic, error handling, protocol and header parsing, cryptographic errors, and random number generators. We also watch for areas where more defensive programming could reduce the risk of future mistakes and speed up future audits. Although our primary focus is on the in-scope code, we examine dependency code and behaviour when it is relevant to a particular line of investigation.

Vulnerability Analysis:
Our methodologies include manual code analysis, user interface interaction, and white box penetration testing. We consider the project's website, specifications, and whitepaper (if available) to attain a high-level understanding of what functionality the smart contract under review contains. We then communicate with the developers and founders to gain insight into their vision for the project. We install and deploy the relevant software, exploring the user interactions and roles. While we do this, we brainstorm threat models and attack surfaces. We read design documentation, review other audit results, search for similar projects, examine source code dependencies, skim open issue tickets, and generally investigate details other than the implementation.

Documenting Results:
We undergo a robust, transparent process for analysing potential security vulnerabilities and seeing them through to successful remediation. When a potential issue is discovered, we immediately create an issue entry for it in this document, even though we have not yet verified the feasibility and impact of the issue. This process is vast because we document our suspicions early even if they are later shown to not represent exploitable vulnerabilities. We generally follow a process of first documenting the suspicion with unresolved questions, and then confirming the issue through code analysis, live experimentation, or automated tests. Code analysis is the most tentative, and we strive to provide test code, log captures, or screenshots demonstrating our confirmation. After this, we analyse the feasibility of an attack in a live system.

Suggested Solutions:
We search for immediate mitigations that live deployments can take and finally, we suggest the requirements for remediation engineering for future releases. The mitigation and remediation recommendations should be scrutinised by the developers and deployment engineers, and successful mitigation and remediation is an ongoing collaborative process after we deliver our report, and before the contract details are made public.

Disclaimers

Hashlock's Disclaimer

Hashlock's team has analysed these smart contracts in accordance with the best industry practices at the date of this report, in relation to: cybersecurity vulnerabilities and issues in the smart contract source code, the details of which are disclosed in this report, (Source Code); the Source Code compilation, deployment, and functionality (performing the intended functions).

Due to the fact that the total number of test cases is unlimited, the audit makes no statements or warranties on the security of the code. It also cannot be considered as a sufficient assessment regarding the utility and safety of the code, bug-free status, or any other statements of the contract. While we have done our best in conducting the analysis and producing this report, it is important to note that you should not rely on this report only. We also suggest conducting a bug bounty program to confirm the high level of security of this smart contract.

Hashlock is not responsible for the safety of any funds and is not in any way liable for the security of the project.

Technical Disclaimer

Smart contracts are deployed and executed on a blockchain platform. The platform, its programming language, and other software related to the smart contract can have their own vulnerabilities that can lead to attacks. Thus, the audit can't guarantee the explicit security of the audited smart contracts.

About Hashlock

Hashlock is an Australian-based company aiming to help facilitate the successful widespread adoption of distributed ledger technology. Our key services all have a focus on security, as well as projects that focus on streamlined adoption in the business sector.

Hashlock is excited to continue to grow its partnerships with developers and other web3-oriented companies to collaborate on secure innovation, helping businesses and decentralised entities alike.
